Contains: Figure S1, Figure S2, Figure S3, Figure S4, Table S1, Table S2, Table S3

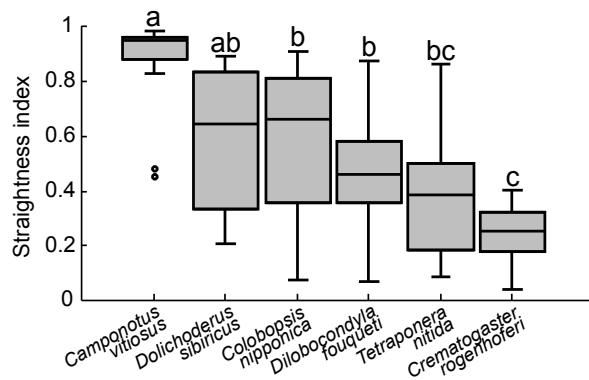

Figure S1. Straightness indices of swimming ants shown in Figure 1, with higher values indicating straighter paths. Large differences are evident between species (overall effect: Wald $\chi^2 = 70.62$, $p < 0.001$; df 5,88). Full statistical results are compiled in Table S1.

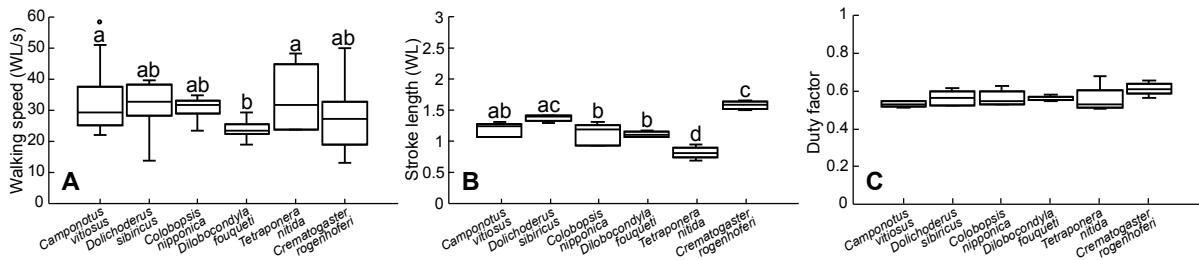

Figure S2. Kinematic parameters of walking ants. Distance measures are normalised to thorax length (Weber's length, WL), as body size varies between species and individuals. **(A)** Walking speed is different among species (overall effect: Wald $\chi^2 = 19.01$, $p < 0.01$; df 5,69) but not for many species comparisons, it is always higher than swimming speed (Fig. 2a). **(B)** Power stroke length (overall effect: Wald $\chi^2 = 222.32$, $p < 0.001$; df 5,30) varies between species and differs from swimming stroke length in most species (Fig. 2b). **(C)** Duty factors show only slight differences (overall effect: Wald $\chi^2 = 13.51$, $p < 0.05$; df 5,30), but not for any species comparisons; they are always higher than in swimming ants (Fig. 2c). Panels (B) and (C) are based on the movements of all six legs over three full strides (5 individuals per species). Full statistical results are compiled in Table S2.

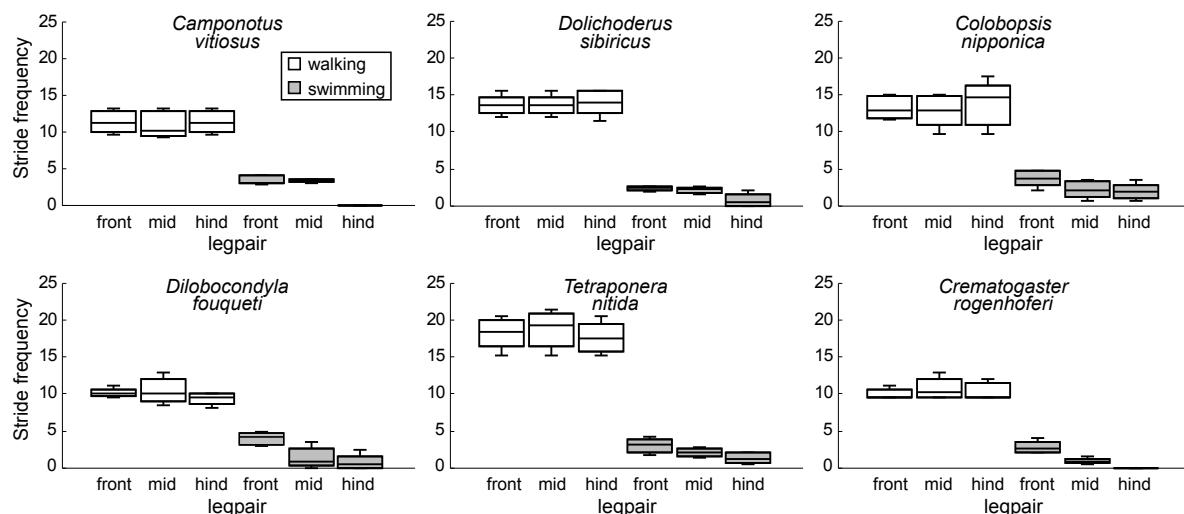

Figure S3. Stride frequency during walking and swimming locomotion for each leg pair separately (front/mid/hind). Frequency is generally much reduced in swimming ants, and legpairs are used asymmetrically for propulsion. The different swimming speeds between species are not caused by differences in average stride frequency, as all species (except *Crematogaster rogenhoferi*) swim with very similar, low stride frequencies. Overall effects (not separated by leg pair): swimming: Wald $\chi^2 = 27.39$, $p < 0.001$; df 5,30; walking: Wald $\chi^2 = 129.79$, $p < 0.001$; df 5,30. Full statistical results are compiled in Tables S1, S2 and S3.

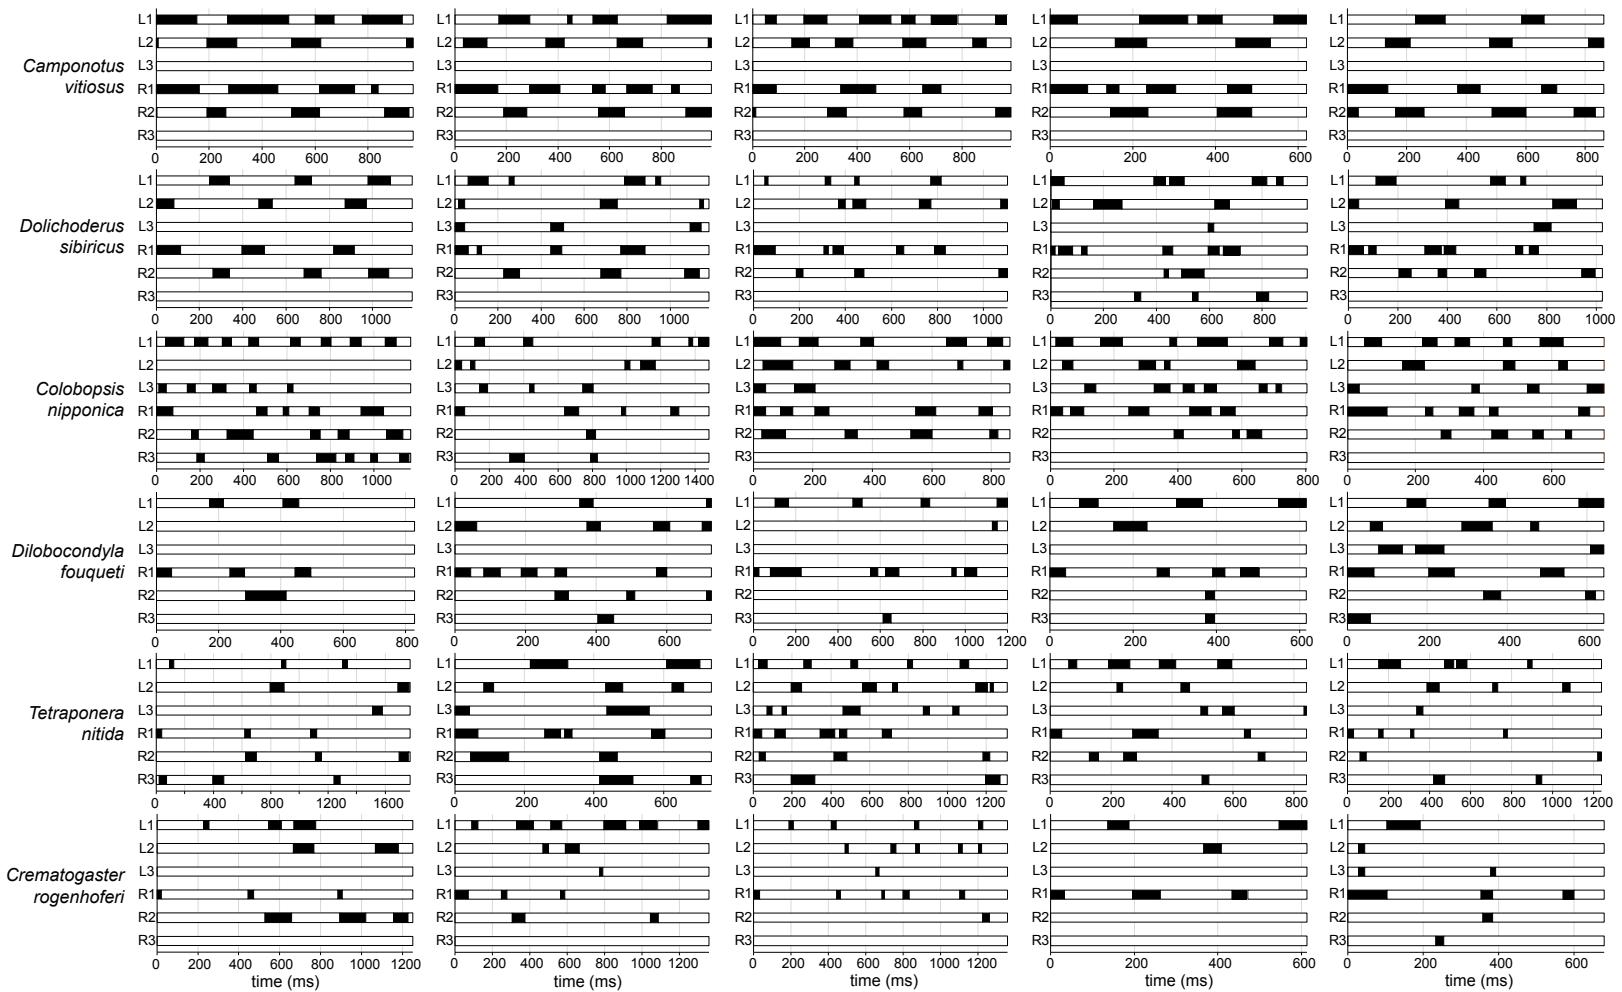

Figure S4. Gait patterns of swimming ants. Each panel shows the gait pattern of a different individual over three full strides of the right front leg (R1). Black bars show backward leg movement, and white bars show forward or no movement. The legs are named according to body side (L for left, R for right) and numbered front to back (1 to 3). The individuals in the first column are the same individuals shown in Figure 3. Despite large inter-individual differences, species-specific patterns in leg usage are visible. Note differences in scale on the time axis.

Table S1: Summary of generalised linear mixed modelling (GLMM) for five swimming kinematic parameters (A) speed, (B) straightness index, (C) stroke length, (D) duty factor and (E) stride frequency. Shown are the model coefficient (Estimate), standard error (SE), *t*-ratio, partial *P* (*p*-value) of the *F*-statistic. Bold values indicate statistical significance. Note: number of observations for speed & straightness index (*n* = 88), for stroke length, duty factor & stride frequency (*n* = 30).
