RUSSELL, J.A. 2012: The ants (Hymenoptera: Formicidae) are unique and enigmatic hosts of prevalent *Wolbachia* (Alphaproteobacteria) symbionts. – Myrmecological News 16: 7-23.

### Appendix 1: supplemental discussion

#### (1) Re-assessing the relationship between *Wolbachia* and modes of colony founding

Given that *Wolbachia* prevalence varies between ant taxa it is important to assess the ecological attributes that correlate with this variation. The original finding of WENSELEERS & al. (1998) on the potential importance of colony founding mode, thus, seems ripe for re-evaluation here, especially in light of the fact that much more screening data has accumulated since this study was published.

To enable this re-assessment, I combined the results of the Wenseleers paper with those from other studies using diagnostic PCR to survey for *Wolbachia* across ants. Literature searches aimed at these surveyed ants identified several with known modes of colony founding. Both attributes are presented in Appendix 3, while the *Wolbachia* presence within dependent vs. independently founding species are illustrated in Figure 2.

To summarize, *Wolbachia* have been found in 26 / 51 (50.9%) species exhibiting dependent modes of colony founding and in 8 / 22 (36.4%) species that found colonies independently. These two values are not significantly different according to a Fisher's Exact Test ( $p = 0.3108$ ). However, the level of infection within the independent class was driven by high *Wolbachia* prevalence among the leaf-cutter ants (i.e., 6 / 6 species infected across the genera *Acromyrmex* and *Atta*; Fig. 2). When these ants are removed from the analysis, only 2 / 16 (12.5%) independently founding species are infected. And it is interesting to note that one of these infected species, *Tetraponera penzigi*, comes from a genus that also appears commonly infected.

Among the dependently founding species, which typically utilized budding or fission, inclusion of data from the highly infected *Formica* genus appears to bias the comparison, as 7 / 7 analyzed dependently founding *Formica* species were *Wolbachia* hosts. But even without these species, the revised total for dependent founders was 19 / 44, or 43.2% infection. This value was still considerably, and significantly higher than that for obligately independent founders without leaf-cutter data (Fig. 2;  $p = 0.0342$ ).

Findings on prevalent infection within *Formica* and leaf-cutter ants suggest the potential for taxon-specific idiosyncrasies that could bias the above analyses – both are likely predisposed for *Wolbachia* infection for reasons that have nothing to do with the mode of colony founding. Future investigations should, thus, take two particular approaches to resolve the relationship between *Wolbachia* infection and mode of colony founding. First, screening should target known independently founding species from multiple taxa to help improve statistical power. Second, researchers should consider the ant phylogeny when performing statistical analyses, helping to account for taxon-specific biases in *Wolbachia* prevalence. To begin such a consideration, I performed a concentrated changes test (MADDISON 1990) in MacClade (MADDISON & MADDISON 2003), using a combined version of two published ant phylogenies (MOREAU & al. 2006, SCHULTZ & BRADY 2008). Data on *Wolbachia* infection and mode of colony founding (i.e., obligately independent vs. all other modes) were added as binary variables, then mapped onto the tree using parsimony. The concentrated changes test then assessed whether gains of *Wolbachia* tended to occur more rarely on branches reconstructed to have independent modes of colony founding. The results indicated a marginally significant trend of fewer *Wolbachia* acquisitions within independently founding lineages than expected by chance ( $p = 0.065$ ), providing partial support for the examined pattern, while reinforcing the idea that more directed sampling is needed to fully resolve this issue.

#### (2) Infection patterns: within species, colonies, and individuals

**Infection within species and populations:** Cross-species infection patterns have obviously brought to light a considerable amount of information regarding the dynamics of ant-*Wolbachia* interactions. In addition to these studies, research on these symbionts has also focused on trends observed at lower hierarchical levels. For starters, work performed across the ants has detected a range of intraspecific infection levels across various species. At the upper end, species from the genera *Acromyrmex* and *Formica* have commonly been shown to harbor *Wolbachia* at high frequencies, approaching 100% infection across colonies in some instances (VAN BORM & al. 2000, WENSELEERS & al. 2002, VILJAKAINEN & al. 2008, FROST & al. 2010). In contrast, research on *Solenopsis* species has more commonly detected polymorphism, with frequencies showing a large extent of variation between populations. The first insights here came from a study by SHOEMAKER

& al. (2000) that performed extensive screening within and across populations of *Solenopsis* species. Six out of nine surveyed species were infected. And of these, four showed evidence for polymorphic infection within populations, with frequencies of infected nests for two well-sampled species ranging from 6-86% across populations. Maternal transmission efficiency was estimated to exceed 99.3% in the wild, suggesting the involvement of other governing factors in driving these trends of polymorphism. In a follow-up study, researchers screened 643 *S. invicta* colonies from 15 populations spanning 11 geographic locations in their native South American range. Four populations were uninfected, while the nests from infected populations harbored the symbiont at frequencies ranging from 2-93% (SHOEMAKER & al. 2003). In accordance with their previous study, the authors found that *Wolbachia* were more prevalent in monogyne populations (i.e., one queen per nest) compared to sympatric polygyne populations. They also observed that these symbionts were more prevalent in southern vs. northern populations, suggesting a recent invasion in the North, different phenotypic effects of strains from different populations, or differences in the environmental factors responsible for shaping the levels of symbiont prevalence (SHOEMAKER & al. 2003, AHRENS & SHOEMAKER 2005).

Another important discovery from research on the *Solenopsis* system was the finding that *Wolbachia* were extremely rare or absent within invasive populations of *S. invicta* and *S. richteri* (SHOEMAKER & al. 2000, BOUWMA & al. 2006, YANG & al. 2010). This phenomenon has also been documented for the invasive Argentine ant, *Linepithema humile*: almost half of the colonies from native populations harbor *Wolbachia* at intermediate frequencies; yet *Wolbachia* have been found in only one out of nearly two-dozen sampled non-native locales (TSUTSUI & al. 2003, REUTER & al. 2005).

Whether these patterns result from drift-mediated symbiont loss, colonization by uninfected queens, or some other mechanism (SHOEMAKER & al. 2000, TSUTSUI & al. 2003, REUTER & al. 2005), the absence of potentially detrimental *Wolbachia* has been proposed to aid in the success of invasive ants in their novel habitats. Under this logic, and assuming that these symbionts are indeed detrimental, the re-introduction of this symbiont should be considered in the development of integrated pest management programs (SHOEMAKER & al. 2000, TSUTSUI & al. 2003). Although this is not an immediate possibility among the ants, *Wolbachia*-driven strategies are being seriously considered for other insects (BRELSFOARD & al. 2009, FU & al. 2010), leaving open the possibility that these symbionts could eventually be used in the fight against harmful ant pests.

**Infection within colonies.** Moving down one level in the hierarchy, it is of great interest to note that some ants from the genera *Acromyrmex*, *Atta*, and *Formica* show infection polymorphism within colonies (VAN BORM & al. 2001, KELLER & al. 2001, WENSELEERS & al. 2002, VILJAKAINEN & al. 2008, FROST & al. 2010). So not only can sibling workers differ with respect to the presence or absence of *Wolbachia* infection, but in some leaf-cutter species, workers may also exhibit lower infection rates than those seen among queens (VAN BORM & al. 2001). While such a trend could be driven by occasional transmission failure, it instead appears that "curing" of *Wolbachia* infections is the more likely explanation (WENSELEERS & al. 2002; but see Box 1 for an alternative explanation). It is currently not clear how broadly these trends extend across the Formicidae, but intracolony variation does not appear common for *Solenopsis* species (SHOEMAKER & al. 2000). Regardless of the breadth of this phenomenon, its novelty, causes, and implications are intriguing, as discussed at greater length in the manuscript.

**Infection within individuals.** At the individual level, a lack of microscopy has limited our knowledge on *Wolbachia* tissue tropism, although SHOEMAKER and colleagues (2000) found *Wolbachia* in the heads, thoraces, and abdomens of *S. invicta* queens. In contrast, the genotyping of strains from individual ants has provided insights into alternative aspect of individual-level infection dynamics – coinfection. To date, the ants' propensity to harbor multiple co-infecting *Wolbachia* strains sets them apart from most other arthropods. Since WENSELEERS and colleagues (1998) first identified multiple infections involving *Wolbachia* from different supergroups (A and B), subsequent studies have utilized cloning and sequencing to better examine the diversity of *Wolbachia* strains within individuals, allowing the discovery of co-infections by strains from single supergroups.

The first of these studies targeted leaf-cutter ants from the tribe Attini, which had previously been shown to harbor *Wolbachia* infections at high frequencies (3 / 3 *Acromyrmex* species and 4 / 4 *Atta* species were infected; VAN BORM & al. 2001). Cloning and sequencing revealed that these ants frequently harbored between three and four strains within individual workers (VAN BORM & al. 2003). In the same year, up to five strains were reported within individual *Formica exsecta* workers (REUTER & KELLER 2003). A more recent study on *Formica* species demonstrated that multiple infection is common within this genus, although most are characterized by two co-inhabiting strains (VILJAKAINEN & al. 2008). Infections with two *Wolbachia* strains have also been detected in *Solenopsis* species (AHRENS & SHOEMAKER 2005, DE SOUZA & al. 2009).

With just one exception – a five strain infection in tephritid flies (JAMNONGLUK & al. 2002) – findings of four to five co-infecting strains were unprecedented when first reported. So it was even more impressive when DEDEINE and colleagues suggested up to eight co-infecting strains within single workers of *Solenopsis daguerrei* (2005). In spite of more recent findings illustrating trends of common multiple infection within some insect groups (e.g., heteropteran bugs – KIKUCHI & FUKATSU 2003, lice – KYEI-POKU & al. 2005), none have surpassed *S. daguerrei* in terms of the number of strains found within single hosts. The causes and consequences of apparently common multiple infection in some ant groups remain mostly unclear. But it is interesting to consider that the presence of multiple *Wolbachia* genomes within single hosts may provide an opportunity for genetic exchange, making ants potential "melting pots" for the *Wolbachia* gene pool.

## Appendix 2: *Wolbachia* infection across arthropod species

Over 91 papers were surveyed to assess the distributions of *Wolbachia* across the arthropods. All studies utilized diagnostic PCR to test for *Wolbachia* across two or more species. Species are reported as positive if infection was detected in at least one individual from the species in one or more studies. The publications corresponding to these screening results are indicated, as are the taxonomic classifications of surveyed hosts, when available. Only the first published finding of infection is cited for infected species surveyed in multiple studies. Although this table generally reports on one result per species, the presence of unidentified and undescribed species in this dataset implies the potential for a small amount of redundancy, and the limited number of individuals screened per potential host also implies that several "negative" species may still be infected.

### Appendix 3: Distribution of *Wolbachia* symbionts across ant species with known modes of colony founding

Data on infection status and colony founding were obtained from a meta-analysis (see Appendix 2 for the bibliography on *Wolbachia* infection; the references used for colony founding data are presented below). Species were declared as obligately dependent founders (i.e., single queens found colonies without the assistance of workers or other queens) if all known colonies utilized this mode of foundation. Nearly all of the non-independent founders here utilize budding or fission.

Genus	Species	<i>Wolbachia</i> infection	Obligate independent founding
<i>Acanthomyrmex</i>	<i>ferox</i>	+	no
<i>Aenictus</i>	<i>javanus</i>	+	no
<i>Aenictus</i>	<i>laeviceps</i>	+	no
<i>Amblyopone</i>	<i>pallipes</i>	-	no
<i>Amblyopone</i>	<i>reclinata</i>	+	no
<i>Anoplolepis</i>	<i>longipes</i>	+	no
<i>Aphaenogaster</i>	<i>senilis</i>	-	no
<i>Cardiocondyla</i>	<i>emeryi</i>	+	no
<i>Cataglyphis</i>	<i>cursor</i>	-	no
<i>Diacamma</i>	<i>rugosum</i>	-	no
<i>Diacamma</i>	sp.	-	no
<i>Dinoponera</i>	<i>gigantea</i>	-	no
<i>Dolichoderus</i>	<i>thoracicus</i>	-	no
<i>Dorylus</i>	<i>laevigatus</i>	-	no
<i>Dorylus</i>	<i>wilverthi</i>	-	no
<i>Eciton</i>	<i>burchellii</i>	-	no
<i>Eciton</i>	<i>hamatum</i>	-	no
<i>Formica</i>	<i>lugubris</i>	+	no
<i>Formica</i>	<i>paralugubris</i>	+	no
<i>Formica</i>	<i>polyctena</i>	+	no
<i>Formica</i>	<i>rufa</i>	+	no
<i>Formica</i>	<i>exsecta</i>	+	no
<i>Formica</i>	<i>truncorum</i>	+	no
<i>Formica</i>	<i>praetensis</i>	+	no
<i>Formicoxenus</i>	<i>provancheri</i>	+	no
<i>Labidus</i>	<i>praedator</i>	-	no
<i>Leptanilla</i>	sp. 1	-	no
<i>Leptanilla</i>	sp. 2	+	no
<i>Leptogenys</i>	<i>diminuta</i>	-	no
<i>Leptogenys</i>	<i>myops</i>	+	no
<i>Leptothorax</i>	<i>rugatulus</i>	-	no
<i>Linepithema</i>	<i>humile</i>	+	no
<i>Myopias</i>	<i>emeryi</i>	+	no
<i>Myrmecina</i>	sp.	-	no
<i>Myoceparus</i>	<i>smithii</i>	-	no
<i>Neivamyrmex</i>	<i>nigrescens</i>	+	no

<i>Odontomachus</i>	<i>rixosus</i>	+	no
<i>Oecophylla</i>	<i>smaragdina</i>	-	no
<i>Onychomyrmex</i>	<i>hedleyi</i>	-	no
<i>Pachycondyla</i>	<i>astuta</i>	-	no
<i>Pheidole</i>	<i>minutula</i>	-	no
<i>Pheidologeton</i>	<i>affinis</i>	+	no
<i>Platythrea</i>	sp.	-	no
<i>Polyergus</i>	<i>breviceps</i>	+	no
<i>Rhytidoponera</i>	<i>metallica</i>	+	no
<i>Sericomyrmex</i>	<i>amabilis</i>	+	no
<i>Solenopsis</i>	<i>geminata</i>	-	no
<i>Solenopsis</i>	<i>invicta</i>	+	no
<i>Tapinoma</i>	sp.	+	no
<i>Tetramorium</i>	<i>kheperra</i>	-	no
<i>Tetramorium</i>	sp.	-	no
<i>Acromyrmex</i>	<i>echinaior</i>	+	yes
<i>Acromyrmex</i>	<i>octospinosus</i>	+	yes
<i>Atta</i>	<i>cephalotes</i>	+	yes
<i>Atta</i>	<i>sexdens</i>	+	yes
<i>Atta</i>	<i>colombica</i>	+	yes
<i>Atta</i>	<i>texana</i>	+	yes
<i>Cyphomyrmex</i>	<i>costatus</i>	-	yes
<i>Cyphomyrmex</i>	<i>longiscapus</i>	-	yes
<i>Gnamptogenys</i>	<i>costata</i>	-	yes
<i>Hypoponera</i>	sp.	-	yes
<i>Lasius</i>	<i>alienus</i>	-	yes
<i>Myopopone</i>	<i>castanea</i>	-	yes
<i>Mystrium</i>	<i>rogeri</i>	-	yes
<i>Odontomachus</i>	<i>simillimus</i>	-	yes
<i>Pheidole</i>	sp.	-	yes
<i>Pheidole</i>	<i>tandjongensis</i>	-	yes
<i>Pogonomyrmex</i>	<i>maricopa</i>	-	yes
<i>Polyrhachis</i>	<i>cryptoceroides</i>	-	yes
<i>Pristomyrmex</i>	<i>brevispinosus</i>	-	yes
<i>Probolomyrmex</i>	<i>dammermani</i>	+	yes
<i>Tetraponera</i>	<i>penzigi</i>	+	yes
<i>Trachymyrmex</i>	<i>cornetzi</i>	-	yes

#### Appendix 4: Candidate phenotypes for *Wolbachia* of ants

Phenotype	Plausibility	Evidence	
		Pros	Cons
Feminization	Unlikely		Feminization of haploid males would lead to the production of sterile haploid queens (WENSELEERS & al. 1998).
Parthenogenesis	Unlikely		<i>Wolbachia</i> -induced chromosomal duplication (the mechanism behind parthenogenesis; STOUTHAMER 1997) would lead to the production of homozygous ants, which would develop as sterile, diploid males (CROZIER 1971, WENSELEERS & al. 1998, SHOEMAKER & al. 2000). <i>Wolbachia</i> have not been detected within any surveyed ants that utilize thelytokous parthenogenesis (WENSELEERS & BILLEN 2000, HIMLER & al. 2009).
Male-killing	Plausible	Male death could free up resources favoring increased production or fitness of queens. Suggested to occur in <i>Acromyrmex</i> species due to lower infection rate in males vs. gynes (VAN BORM & al. 2001).	The male infection rate in <i>A. echinator</i> (59%; VAN BORM & al. 2001) was over fifteen times higher than levels reported for male-killing <i>Wolbachia</i> in natural populations of other species ( <i>Acraea encedon</i> : 0% male infection, JIGGINS & al. 2002b; <i>Hypolimnas bolina</i> : 3.78% male infection, CHARLAT & al. 2005; <i>Drosophila innubila</i> : 1.86% male infection, DYER & al. 2005). So perhaps the low male infection rate is related to the phenomenon driving low infection rates in workers of this species. There is no precedent for male-killing <i>Wolbachia</i> in any hymenopteran (but see GHERNA & al. 1991, for male-killing by <i>Arsenophonus</i> ). Male-killing was argued against in <i>Solenopsis invicta</i> and <i>Formica truncorum</i> due to similar numbers of infected males and queens (WENSELEERS & al. 2002, BOUWMA & al. 2006).
Cytoplasmic incompatibility	Plausible	It is the most prevalent phenotype executed by Super-group A and B <i>Wolbachia</i> (WERREN & al. 2008). The phenotype has been documented in several hymenopterans (e.g., VAVRE & al. 2000). Theoretical models (FRANK 1998) suggest that frequent multiple infections (REUTER & KELLER 2003, VAN BORM & al. 2003, DEDEINE & al. 2005, DE SOUZA & al. 2009) could be driven by CI. High prevalence infections in some populations (KELLER & al. 2001, VAN BORM & al. 2001, WENSELEERS & al. 2002, DE SOUZA & al. 2009) are theoretically consistent with CI (TURELLI 1994).	Some populations harbor low frequency infections (SHOEMAKER & al. 2000, SHOEMAKER & al. 2003, TSUTSUI & al. 2003, REUTER & al. 2005) that fall below equilibrium levels predicted under models of CI (e.g., TURELLI 1994). In some instances, similar infection levels across populations suggest that these infection levels may be at equilibrium (AHRENS & SHOEMAKER 2005), arguing against the possibility that they could represent early stage invasions. CI may be unlikely in <i>Acromyrmex echinator</i> and <i>A. octospinosus</i> due to low estimated transmission rates (VAN BORM & al. 2001).
Production of split sex ratios	Unlikely		<i>Wolbachia</i> were not enriched in colonies with greater female production in <i>Formica exsecta</i> or <i>F. truncorum</i> (KELLER & al. 2001, WENSELEERS & al. 2002). Other species with split sex ratios have screened negative for <i>Wolbachia</i> (e.g., DEBOUT & al. 2010).
Curing / Loss (potentially beneficial loss from adult workers)	Highly likely	Adult worker infection rates in <i>Formica truncorum</i> are considerably lower than infection rates seen among worker pupae (WENSELEERS & al. 2002). <i>F. exsecta</i> exhibit similar patterns of higher prevalence in pupae vs. adult workers (KELLER & al. 2001). Some <i>Acromyrmex</i> and <i>Atta</i> species show infection polymorphism within colonies (FROST & al. 2010). Two <i>Acromyrmex</i> species have higher rates of infection in queens vs. adult workers (VAN BORM & al. 2001). Since infection may come with a fitness cost (WENSELEERS & al. 2002), loss from workers (which will not transmit <i>Wolbachia</i> ) may be adaptive for both the host and symbiont.	Higher mortality of infected workers could lead to similar patterns. However, the number of deaths required seems unrealistic. Furthermore, findings of increased sexual production in colonies with lower worker infection rates (WENSELEERS & al. 2002) are not consistent with this mechanism.
Fitness costs	Likely	May occur in <i>Formica truncorum</i> since sexual production (i.e., sexual biomass produced per worker) was higher in colonies with lower worker infection rates (WENSELEERS & al. 2002). Intermediate frequencies in <i>Solenopsis invicta</i> (in spite of high transmission rates; SHOEMAKER & al. 2003) are	

		consistent with conditional costs and benefits, and maintenance of symbionts through balancing selection.	
Defense against natural enemies	Plausible	Precedent for protection against RNA viruses in other insects (HEDGES & al. 2008, TEIXEIRA & al. 2008). <i>Wolbachia</i> induce antimicrobial gene expression and have detrimental effects on <i>Plasmodium</i> and nematodes within mosquitoes (KAMBRIS & al. 2009, 2010). <i>Solenopsis invicta</i> are infected by virulent RNA viruses. The frequencies of these viruses and <i>Wolbachia</i> symbionts vary between populations (VALLES & al. 2009, YANG & al. 2010).
